

You Abuse, You Lose

If your computer suddenly loses data or locks up, the culprit may be a worn out or damaged LAN (local area network) data coax cable—one that's been abused during one too many computer moves.

It's that bent, broken or twisted coax cable that links you to the network server and the information highway.

It gives you access to vital army information on publications, supply and maintenance, and to your e-mail.

So don't roughhouse the computer during spring cleaning, office and workstation moves or trips to the field.

If your cable isn't damaged yet, do a little PM and have your support shop add some heat shrink tubing, NSN 5970-00-032-0291, where the connector and the cable meet.

If the cable is already damaged, get it repaired or local purchase a new 10 base-2, 50-ohm coax cable assembly.
