# SET FOR COLD WEATHER

The alcohol reservoir under the excavator's rear wheel well (curbside) takes a beating from thrown rocks, the elements, and the age of the vehicle.

This reservoir is part of the vehicle's compressed air system antifreeze unit. The unit shoots ethyl alcohol into the air system to keep water from freezing in the air lines.

A crack or hole in the reservoir's plastic housing means it won't hold alcohol. Without alcohol, water freezes in the air system. Air system failure is the end result.

So before you add alcohol to the system, make sure the reservoir can hold its own.

## The Right Position

You'll also want to make sure the air line antifreeze unit is set to the number 1 (open) position for cold weather.

And keep the reservoir filled, even in summer, so dirt and dust can't get in the system.
